イロト イヨト イヨト イヨト

- Microbial ecosystem = population of bacteria that interact in a given environment
  - $\hookrightarrow$  Exple : soil, sea water, **gut**
- A varying proportion of bacteria are not genotyped neither cultivable.
- Before metagenomics : analysis of bacteria culture.
- Metagenomics = analysis of bacterial genes in a given biological sample.
  (≠ genomics = analysis of the genome of a given organism)
- Metagenomics made possible by technological advances.
  → NGS (next generation sequencing)

Meta-omics data = omics data measured on a population of bacteria in a given environment.

- Metagenomics data = DNA of bacteria. Two types of measures :
  - only 16S gene, characteristic of the species
  - all genes (Whole Genome Sequencing)

 $\hookrightarrow$  widely studied

- Meta-transcriptomics data = RNA of bacteria
- Meta-proteomics data = proteins of bacteria
  → New

DNA genomics	$\rightarrow$	RNA transcriptomics	$\rightarrow$	proteins proteomics	$\rightsquigarrow$	function metabolomics

# Metagenomics WGS (Whole Genome Sequencing) or shotgun

## Next generation sequencing

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

## Construction of a catalogue from a large number of sample

 $\hookrightarrow$  In gut, Metahit catalogue = 10 millions of genes.

## • Compute metagenomic abundances in a biological sample :

Abundance of gene  $g = \frac{\text{counts of gene } g}{(\text{length of gene } g) \times (\#\text{reads mapped})}$ 

## • Characteristics of the data

- High technical variability
- ◊ Very large dimension : log(p)>n
- In gut, 200-500,000 genes present in each sample : high sparsity

## Dimension reduction

- Grouping of genes based on sequence (similarity between proteins translated in sillico) : COG (Cluster of Orthologous Genes)
  - $\hookrightarrow$  Functional grouping.
- ◊ MGS (MetaGenomics Species) : grouping by covariance of abundances.
- $\diamond~$  Gene annotation (KEGG) : bank of genes whose function has been identified.
  - $\hookrightarrow$  Limited to known bacterial genes.

イロト スポト メヨト メヨト

# 16s metagenomics data

- 16s : gene characteristic of species
- Data : matrix of abundances of bacterial species (100/1000 variables)
- Phylogenetic tree : tree that represents evolutionnary relashionships between species.
  - $\hookrightarrow$  built from distances between the nucleotide sequences of 16s genes.

 $\hookrightarrow$  Structure in variables.

(D) (A) (A) (A)

## • 16S

- Less expensive
- $\diamond~$  More widely used ( $\Rightarrow~$ more specific statistical methods)
- Less technical variability.
- ◇ Ecology issues : present/absent species in given conditions, co-presence...

## • WGS

- Large number of variables
- High technical variability
- Functional analysis.

**Controverse** : phylogenetic grouping correspond approximately to functional grouping

To sum up, metagenomics data are :

- of large/very large dimension
- (very) noisy
- highly correlated
- sparse
- potentially structured

æ

- Meta-transcriptomics : similar to metagenomics
- Meta-proteomics and metabolomics : Technologies similar to omics (GC-MS, MS-MS)
  - Fractionning of molecules (metabolites/proteins) in fragments (ions/peptides)
  - Identifications of fragments by their M/Z spectra compared to a bank of peptides/ions
  - Recovering of molecules abundances.

 $\frac{\text{Difficulty}}{\text{present in few biological samples}}.$

2 Sequencing of metagenomics data

#### 3 Statistical analysis of metagenomics data

Some of my topics of interest

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・

- **Ecology** : description of species present in the environment.
  - Difference between conditions (ex :comparison of soil samples from different geographics area)
  - Co-presence of species.
- Functionality : how does microbiote works?
  - Interactions between bacteria
  - Link between microbiote and phenotypes/omics data
- $\hookrightarrow$  Related statistical questions may be unprecised.

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・

# Usual statistical approaches

- Multiple testing (differential analysis)
  - zero-inflated parametric models.
  - o permutation tests [White et al, PLoS Comput. Bio. 2009]
- Mixed models (multiple time-points) [Le Cao et al 2015]

$$\begin{aligned} X_i^j(t) = \underbrace{f_j(t)}_{\text{time effect :}} &+ \underbrace{\alpha_i^j + \beta_i^j t}_{\text{random individual}} &+ \varepsilon_{i,j}(t) \\ & \text{splines} & \text{effect} \end{aligned}$$

- Adaptation of multivariate analysis methods
  - Centered Log-Ratio transformation + methods based on correlation (PLS...)
  - Variance decomposition (multi-sites measurements)
  - Methodes based on distance matrices
  - Penalisation contraining structure based on phylogenic trees [Chen 2012]
- Variables selection by sparse multivariate methods
- Bi-clustering : Non-negative Matrix Factorization
- Network inference : GGM

• Goal : test the effect of race on rumen microbiote for cow.

• Data :

- $\diamond~(X_{u,k}),~u=1,\ldots,N,~k=1,\ldots,p:$  16S measurement of abundances in p bacterial species for N cows
- $\land Y_u \in \{1, \ldots, a\}$  : races
- ◇ "ANOVA" notations :  $X_{i,j,k}$  : i = 1, ..., a : category (race) j = 1, ..., n : repetition (cow) k = 1, ..., p : variable (species)

• Goal : test the effect of race on rumen microbiote for cow.

• Data :

- $\diamond~(X_{u,k}),~u=1,\ldots,N,~k=1,\ldots,p$  : 16S measurement of abundances in p bacterial species for N cows
- $\diamond \ Y_u \in \{1, \dots, a\} : \mathsf{races}$
- Unifrac distance based on phylogeny between 2 16S samples.

(ロ) (部) (E) (E) (E)

• Goal : test the effect of race on rumen microbiote for cow.

• Data :

- $\diamond~(X_{u,k}),~u=1,\ldots,N,~k=1,\ldots,p$  : 16S measurement of abundances in p bacterial species for N cows
- $\land Y_u \in \{1, \dots, a\}$  : races
- Unifrac distance based on phylogeny between 2 16S samples.

• Goal : test the effect of race on rumen microbiote for cow.

• Data :

- $\diamond~(X_{u,k}),~u=1,\ldots,N,~k=1,\ldots,p$  : 16S measurement of abundances in p bacterial species for N cows
- $\land Y_u \in \{1, \dots, a\}$  : races
- Unifrac distance based on phylogeny between 2 16S samples.

• Geometric MANOVA :

$$SS_W = \sum_{i=1}^{a} \sum_{j=1}^{n} \sum_{k=1}^{p} (X_{i,j,k} - X_{i,\cdot,k})^2 = \frac{1}{n} \sum_{\mathsf{pairs}(u,v)} d_{u,v}^2 \delta_{u,v}$$

with  $d_{u,v}$  the euclidean distance between  $X_u$  et  $X_v$  and

$$\delta_{u,v} = \begin{cases} 1 & \text{if } (u,v) \text{ in same category} \\ 0 & \text{otherwise} \end{cases}$$

$$SS_T = \sum_{i=1}^{a} \sum_{j=1}^{n} \sum_{k=1}^{p} (X_{i,j,k} - X_{\cdot,\cdot,k})^2 = \frac{1}{N} \sum_{\mathsf{pairs}(u,v)} d_{u,v}^2$$

#### • PERMANOVA :

- $\diamond \ d_{u,v}$  replaced by  $D_{u,v}$
- $\diamond$  Test statistic :  $SS_W/SS_T$
- $\diamond$  Distribution under  $H_0$  : permutations

臣

# Nonnegative Matrix Factorization (NMF)

## The NMF model : an interpretable dimension reduction

- $X^{n,p}$  matrix of abundances in p metagenomic groups in n samples.
- Hypothesis :
  - $\diamond$  Abundances organised in  $k \ll \min(n, p)$  pathways  $h_1, \ldots h_k$  characterised by their proportion in metagenomic groups

$$h_{\ell} = (H_{\ell,1}, \ldots, H_{\ell,p})$$

 $\diamond$  Samples  $i = 1, \dots, n$  carcterised by their abundances in pathways :

$$w_i = (W_{i,1}, \ldots, W_{i,k})$$

Therefore

 $X \approx WH$ 

with  $W, H \ge 0$ .

$$\arg\min_{W,H \ge 0} D(X, WH) + pen(W) + pen(H)$$

• Matrix distance  $D \leftrightarrow \mathsf{log}\mathsf{-likelihood}$  of a parametric model

$$X_{i,j} \sim \mathcal{N}\left((WH)_{i,j}, \sigma^2\right) \Leftrightarrow \mathsf{LL}=D_{Frob}(X, WH) + cte$$

 $\diamond X_{i,j} \sim \mathcal{P}\left((WH)_{i,j}\right) \Leftrightarrow \mathsf{LL}=D_{KL}(X,WH) + cte$ 

 $\hookrightarrow$  In practice : choice of distance depends on the field (signal theory : KL, genomics : Frobenius)

- Selection of dimension k of the reduced space : several empirical criteria
- Choice of penalisation (ex : favour sparse pathways)
- Algorithm : alternated minimisation/decreasing of the criterion (bi-convex)

**Comment** : Under constraints that individual profiles  $w_i$  have one non-zero term, the minimsation problem is equivalent to k-means

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへの

## NMF in literature

- In omics, NMF often used for bi-clustering
- Methodological research : mainly algorithmic
- To my best knowlegde, no theoretical analysis with a statistical point of view.
- **PhD** : Inferring agregated functional traits from metagenomics data : application to fiber digestion in gut microbiota [Sebastien Raguideau, 2016]
  - Select groups of genes that catalyse elementary reactions associated to fiber digestion (KEGG)
  - ◊ Build a graph of constraints based on metabolites degradated and produced by elementary reactions
  - Build agregated functional traits by NMF under constraints of connectivity on the graph.

・ロト ・ 日 ・ ・ 目 ・ ・ 日 ・ ・

**1** Presentation of meta-omics

2 Sequencing of metagenomics data

3 Statistical analysis of metagenomics data

4 Some of my topics of interest

・ロン ・四と ・ヨン ・ヨン

- Definition of a statistical model
- Analysis of criteria of selection of  $\boldsymbol{k}$
- Issue 1 : non-unicity of decomposition (W, H) ( "ill-posed" problem )  $\hookrightarrow$  Sufficient criterion for unicity : rows of H orthogonal.
- Issue 2 : general approach?
  - $\diamond$  Assume a predefined number k of pathways? (parametric point of view)
  - $\diamond~$  Compromise bias/variance, reconstruction/stability, where optimal k depends on  $n\,?$  (nonparametric point of view)

# Meta-proteomics data : use of technical replicates

• Proteocardis project : 150 biological samples/4 pathologies, 8 samples with 6 technical replicates.

 $\hookrightarrow$  first large scale project (shotgun - 200 biological samples)

- Goal of the project : discriminant analysis /variable selection.
- Secondary goal : characterise technical variability in meta-proteomics data
  - ♦ Exple : thresholding of low counts :  $X_{i,j}^r$  (sample i = 1, ..., n, variable j, replicate r), estimate

$$p_a = P[X_{i,j}^r = 0 | X_{i,j}^{r'} = a, r \neq r']$$

Question : Use of technical replicates in variable selection

- General idea : variations between replicates provide a "level" for the significance of biological difference.
- Mixed models?
- Multivariate analysis?
