Motivation

Modeling of a spatial phenomenon when data are sampled counts

- A regular grid of quadrats A_1, \dots, A_N on a $\mathcal{D} \subset \mathbb{R}^2$
- We observe Y_i the count in quadrat $i \in \mathcal{O} \subset \mathcal{V} = \{1, \dots, N\}$

Motivation

Such type of data (counts associated with spatial point processes) are encountered in various fields of applications :

- forestry (counts of trees of a given species)
- ecology (sightings of wild animals)
- epidemiology (disease mapping based on reported infection cases)
- environmental sciences (radioactivity counts)
- agronomy (counts of weeds)
- etc ...

Discussion

The log-Gaussian Cox process is often used for modeling this type of data.

1. We derive the parameters estimations by a moments method
2. We propose a MCEM algorithm
3. We present a preliminary comparison
4. We propose a VEM and a VBEM algorithm
5. We present some simulation results

Poisson process

We consider a spatial Poisson process in \mathbb{R}^2 with intensity $\lambda = \{\lambda(x), x \in \mathcal{D}\}$.

- $Y_i \sim \mathcal{P}(\Lambda_i)$ with $\Lambda_i = \int_{A_i} \lambda(x) dx$
- Non stochastic $\Lambda_i \Rightarrow Y_i \perp Y_j$ for $i \neq j \Rightarrow$ No statistical correlation between Y_i and Y_j for $i \neq j$
- In practice
 - there may exist a stochastic dependence between the numbers of points observed in non-overlapping domains
 - the intensity of the point process is often uncertain in areas without data

\Rightarrow More convenient and more parsimonious to use a stochastic modeling of this intensity

Discussion

Cox process

We consider a spatial Poisson process in \mathbb{R}^2 with stochastic intensity $\lambda = \{\lambda(x), x \in \mathcal{D}\}$.

- $\lambda(x) = \exp(\beta) \exp(S(x))$
- $S(\cdot)$ is a Gaussian random field centered with variance σ^2 and exponential covariance function

$$\text{Cov}(S(x_1), S(x_2)) = \sigma^2 \exp(-\alpha \|x_1 - x_2\|)$$

- $Y_i | \Lambda_i \sim \mathcal{P}(\Lambda_i)$ with $\Lambda_i = \int_{A_i} \lambda(x) dx$ approximated by $\Lambda_i = |A_i| \exp(\beta) \exp(S_i)$ where S_i is the value of S at the center of A_i .
- $Y_i | \Lambda_i \perp Y_j | \Lambda_j$ for $i \neq j$.
- 3 parameters in the model $\theta = (\beta, \sigma, \alpha)$, $\beta \in \mathbb{R}$, $\alpha, \sigma \in \mathbb{R}_+^*$.

Variational
methods

VEM algorithm

VBEM
algorithm

Simulations

Discussion

By straightforward calculations we obtain :

$$E(Y_i) = |A_i| \exp(\sigma^2/2) \exp(\beta) \quad (1)$$

$$\begin{aligned} \text{Var}(Y_i) &= |A_i| \exp(\sigma^2/2) \exp(\beta) \\ &+ |A_i|^2 \exp(\sigma^2) \exp(2\beta) (\exp(\sigma^2) - 1) \end{aligned} \quad (2)$$

$$E(Y_i Y_j) = |A|^2 \exp(2\beta) \exp(\sigma^2(1 + e^{-\alpha r})) \quad (3)$$

where $r = |i - j|$

β and σ^2 estimations

By equations (1) and (2) :

$$\sigma^2 = \ln \left[\frac{\text{Var}(Y) - E(Y) + E(Y)^2}{E(Y)^2} \right] \quad (4)$$

$$\beta = \ln \left[\frac{E(Y)}{|A| \sqrt{\frac{\text{Var}(Y) - E(Y) + E(Y)^2}{E(Y)^2}}} \right] \quad (5)$$

$Y_i, \forall i$, are identically distributed. By the weak law of large number, $E(Y_i)$ and $\text{Var}(Y_i)$ are estimated by $\bar{Y} = \frac{1}{\#\mathcal{O}} \sum_{i \in \mathcal{O}} Y_i$

$$\text{and } \hat{V}(Y) = \frac{1}{\#\mathcal{O}} \sum_{i \in \mathcal{O}} (Y_i - \bar{Y})^2$$

$\Rightarrow \hat{\beta}$ and $\hat{\sigma}^2$ are obtained by replacing $E(Y_i)$ and $\text{Var}(Y_i)$ by \bar{Y} and $\hat{V}(Y)$ in (4) and (5).

α estimation

Using equation (3) we obtain :

$$\hat{\alpha} = -\frac{1}{r} \ln \left[\frac{1}{\hat{\sigma}^2} \ln \left[\frac{\hat{E}(Y_i Y_j)}{|A_i|^2 \exp(2\hat{\beta})} \right] - 1 \right]$$

$E(Y_i Y_j)$ is estimated by using the variogram estimation.

Indeed, since :

$$\begin{aligned} \gamma(r) &= \frac{1}{2} \text{Var}(Y(x) - Y(x+r)) \\ &= \text{Var}(Y) - \text{Cov}(Y(x), Y(x+r)) \end{aligned}$$

We easily deduce

$$\hat{E}(Y_i Y_j) = \text{Var}(\hat{Y}) - \hat{\gamma}(r) + \bar{Y}^2$$

where :

$$\hat{\gamma}(r) = \frac{1}{2\#\mathcal{O}_r} \sum_{\mathcal{O}_r} (Y_i - Y_j)^2$$

Discussion

- E-step : Calculation of $p(s, y_{\bar{O}}|y_{O}, \theta^{(t)})$
- M-step :

$$\operatorname{argmax}_{\theta} F(\theta|\theta^{(t)}) = \operatorname{argmax}_{\theta} E \left[\ln p(S, y_{O}, Y_{\bar{O}}|\theta)|y_{O}, \theta^{(t)} \right]$$

How to simulate from $p(s|y_{\mathcal{O}}; \theta^{(t)})$?

How to simulate from $p(s|y_{\mathcal{O}}; \theta^{(t)})$?

We use the algorithm given by Emery and Hernandez (Computers & Geosciences , 2010)

1. Simulate from $p(s_{\mathcal{O}}|y_{\mathcal{O}}; \theta^{(t)})$ (Gibbs sampler)
2. Simulate from $p(s_{\bar{\mathcal{O}}}|s_{\mathcal{O}})$ (easy using any multivariate Gaussian simulation algorithm)

Discussion

The Gibbs sampler

The Gibbs sampler consists in iterating for $i \in \mathcal{O}$:

1. Simulate $S_i | S_{\mathcal{O}-i}$. Let s'_i denote the new simulated value of S_i
2. Simulate a uniform random variable U on $[0, 1]$.
3. If $p_i U < p'_i$ substitute s'_i for s_i

where :

$$\begin{aligned} p_i &= P[Y_{\mathcal{O}} = y_{\mathcal{O}} | S_i = s_i, S_{\mathcal{O}-i} = s_{\mathcal{O}-i}] \\ &= \exp(-\Lambda_i) \frac{\Lambda_i^{y_i}}{y_i!} \prod_{j \in \mathcal{O}-i} \exp(-\Lambda_j) \frac{\Lambda_j^{y_j}}{y_j!} \end{aligned}$$

$$\begin{aligned} p'_i &= P[Y_{\mathcal{O}} = y_{\mathcal{O}} | S_i = s'_i, S_{\mathcal{O}-i} = s_{\mathcal{O}-i}] \\ &= \exp(-\Lambda'_i) \frac{\Lambda'_i{}^{y_i}}{y_i!} \prod_{j \in \mathcal{O}-i} \exp(-\Lambda_j) \frac{\Lambda_j^{y_j}}{y_j!} \end{aligned}$$

Discussion

M step : β and σ^2 update

Solving $\frac{\partial F}{\partial \beta} = 0$ and $\frac{\partial F}{\partial \sigma^2} = 0$ leads to :

$$\beta^{t+1} = \ln \left[\frac{\sum_{i \in \mathcal{O}} y_i + \sum_{i \in \bar{\mathcal{O}}} \hat{y}_i^{(t+1)}}{\sum_{i=1}^N |A_i| \int \exp(s_i) p(s|y_{\mathcal{O}}, \theta^{(t)}) ds} \right]$$
$$\sigma^{2(t+1)} = \frac{1}{N} \int s U^{-1} s^T p(s|y_{\mathcal{O}}, \theta^{(t)}) ds$$

where :

$$\begin{aligned} \hat{y}_i^{(t+1)} &= \int y_i p(s, y_{\bar{\mathcal{O}}}|y_{\mathcal{O}}, \theta^{(t)}) ds dy_{\bar{\mathcal{O}}} \\ &= \int y_i p(y_{\bar{\mathcal{O}}}|s, y_{\mathcal{O}}, \theta^{(t)}) p(s|y_{\mathcal{O}}, \theta^{(t)}) ds dy_{\bar{\mathcal{O}}} \\ &= \exp(\beta^{(t)}) |A_i| \int \exp(s_i) p(s|y_{\mathcal{O}}, \theta^{(t)}) ds \end{aligned}$$

M step : α update

$$\frac{\partial F}{\partial \alpha} = \int p(s, y_{\bar{O}} | y_{\mathcal{O}}, \theta^{(t)}) \left[-\frac{1}{2} \frac{\partial \ln |U|}{\partial \alpha} - \frac{1}{2\sigma^2} s \frac{\partial (U^{-1})}{\partial \alpha} s \right] ds dy_{\bar{O}}$$

Following Searle (1982) :

$$\frac{\partial \ln |U|}{\partial \alpha} = \text{tr} \left[U^{-1} \frac{\partial U}{\partial \alpha} \right]$$

$$\frac{\partial U^{-1}}{\partial \alpha} = -U^{-1} \frac{\partial U}{\partial \alpha} U^{-1}$$

So $\frac{\partial F}{\partial \alpha} = 0 \Leftrightarrow$

$$\text{tr} \left(U^{-1} \frac{\partial U}{\partial \alpha} \right) = \frac{1}{\sigma^2} \int s (U^{-1} \frac{\partial U}{\partial \alpha} U^{-1}) s^T p(s | y_{\mathcal{O}}, \theta^{(t)}) ds$$

solved by a Newton-Raphson algorithm

Discussion

Variational methods for estimation

We can prove that for any distribution $q_s(s)$ on the hidden variables :

$$\begin{aligned}\ln p(y|\theta) &\geq \int q_s(s) \ln p(s, y|\theta) ds - \int q_s(s) \ln q_s(s) ds \\ &\equiv \mathcal{F}(q_s(s), \theta)\end{aligned}$$

The EM algorithm can be written

- E step : $q_s^{(t+1)} = \operatorname{argmax}_{q_s} \mathcal{F}(q_s(s), \theta^{(t)})$
- M step : $\theta^{(t+1)} = \operatorname{argmax}_{\theta} \mathcal{F}(q_s^{(t+1)}(s), \theta)$

For the E step the exact solution is $q_s^{(t+1)} = p(s|y, \theta^{(t)})$.

For the M step the solution is

$$\theta^{(t+1)} = \operatorname{argmax}_{\theta} E[\ln p(S, y|\theta) | y, \theta^{(t)}]$$

VBEM
algorithm
Simulations

Discussion

- Too difficult to evaluate the distribution $p(s|y, \theta)$

⇒ choose a family \mathcal{Q} of (tractable) distributions

- E step : $q_s^{(t+1)} = \operatorname{argmax}_{q_s \in \mathcal{Q}} \mathcal{F}(q_s(s), \theta^{(t)})$
- M step : $\theta^{(t+1)} = \operatorname{argmax}_{\theta} \mathcal{F}(q_s^{(t+1)}(s), \theta)$

- Interest : much faster than MCMC solutions

VBEM algorithm

We can prove that for any distribution $q_s(s)$ on the hidden variables :

$$\begin{aligned}\ln p(y|\theta) &= \ln \int \int p(s, y, \theta) ds d\theta \\ &\geq \ln p(y) - KL(q_{s,\theta}(\cdot) | p_{s,\theta}(\cdot|y))\end{aligned}$$

- We choose separable distributions $q_{s,\theta}(\cdot) = q_s(s)q_\theta(\theta)$
- $q_s(s)$ is an approximation of $p(s|y)$
- $q_\theta(\theta)$ is an approximation of $p(\theta|y)$ We note :

$$\begin{aligned}\ln p(y) &\geq \ln p(y) - KL(q_{s,\theta}(\cdot) | p_{s,\theta}(\cdot|y)) \\ &\equiv \mathcal{F}(q_s(s), q_\theta(\theta))\end{aligned}$$

- E step : $q_s^{(t+1)} = \operatorname{argmax}_{q_s \in \mathcal{Q}} \mathcal{F}(q_s(s), q_\theta^{(t)}(\theta))$
- M step : $q_\theta^{(t+1)} = \operatorname{argmax}_{q_\theta \in \mathcal{Q}'} \mathcal{F}(q_s^{(t+1)}(s), q_\theta(\theta))$

Discussion

Result : explicit expression for $q_{S_j}(S_j), j = 1 \dots N$ but not a classical distribution :

$$q_{S_j}(S_j) \propto \exp(-\mathbf{E}_{q_\theta}[e^\beta]e^{S_j}|A_j| + Y_j S_j) \exp\left(-\frac{(S_j - m_j)^2}{2\sigma_j^2}\right)$$

$$\text{where } \forall j = 1 \dots N, \sigma_j^2 = \frac{1}{\mathbf{E}_{q_\theta}[(\Sigma^{-1})_{jj}]}$$

$$\text{and } \forall j = 1 \dots N, m_j = -\sigma_j^2 \sum_{l \neq j} \mathbf{E}_{q_\theta}[(\Sigma^{-1})_{jl}] \mathbf{E}_{q_{S_l}}[S_l]$$

Problem : how to compute $\mathbf{E}_{q_{S_j}}[S_j]$, $\mathbf{E}_{q_{S_j}}[S_j^2]$ and $\mathbf{E}_{q_{S_j}}[\exp(S_j)]$ needed for the M step ?

E step : proposition

$$\forall j = 1 \dots N,$$

$$\begin{aligned} E_{q_{S_j}}[S_j] &= \int K \exp(-E_{q_\theta}[e^\beta] e^{S_j} |A_j| + Y_j S_j) \exp\left(-\frac{(S_j - m_j)^2}{2\sigma_j^2}\right) \\ &= E_{\mathcal{N}(m_j, \sigma_j^2)}[K' \exp(-E_{q_\theta}[e^\beta] e^{S_j} |A_j| + Y_j S_j) S_j] \end{aligned}$$

→ Monte-Carlo estimation

E step

iterate on

- 1 estimation of $E_{q_{S_j}}[S_j], j = 1 \dots N$ from simulations according to $\mathcal{N}(m_j, \sigma_j^2)$
- 2 evaluation of $m_j, j = 1 \dots N$ from the $E_{q_{S_j}}[S_j], j = 1 \dots N$

evaluation of the other quantities ($E_{q_{S_j}}[S_j^2]$ and $E_{q_{S_j}}[\exp(S_j)]$) again from simulations according to $\mathcal{N}(m_j, \sigma_j^2)$
